

Supervised learning: classification problems

Filippo Biscarini (CNR, Milan, Italy)

filippo.biscarini@cnr.it

Classification problems

- the response variable y is qualitative
- e.g.: coat colour, type of rice (Tropical japonica, Indica, Temperate japonica, Aromatic, Aus)
- special case → binary traits (e.g. cases/controls, resistant/susceptible)
- y = label (a.k.a. dependent variable)
- X = matrix of features (continuous, categorical)

Classification problems

- y = label (a.k.a. dependent variable)
- X = matrix of features (continuous, categorical)
- we don't model the response (y) directly, rather its probability:
 P(y=k|X)
- probabilities lie in [0,1] (not +/- infinity)

Classification problems

classifier:

- K classes (k ∈ K)

probabilities

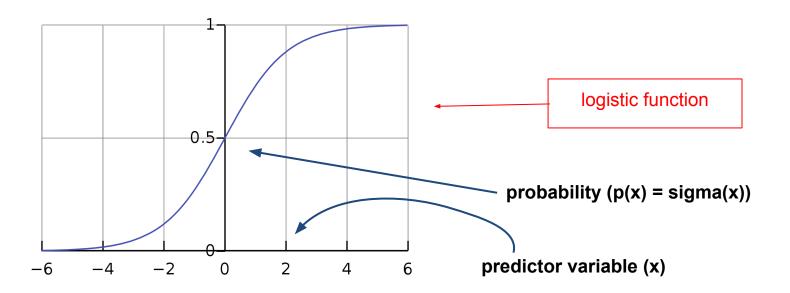

classifier

$$p_k(x) = Pr(y = k|X = x) = f(x)$$

$$C(x)=k,$$
 if $p_k(x)=max\{p_1(x),p_2(x),\ldots,p_K(x)\}$

Binary classification problems

$$\sigma(x) = rac{1}{1 + e^{-x}} = rac{1}{1 + rac{1}{x}} = rac{e^x}{1 + e^x}$$

- the logistic function is the basis for logistic regression
- P(y=1|x) [also p(x)]
- $Z = \beta_0 + \beta_1 x$

$$p(y=1|x)=\sigma(z)=rac{e^{eta_0+eta_1x}}{1+e^{eta_0+eta_1x}}$$
 we see here the familiar model coefficients to be estimated and then used for predictions

a little bit of algebra:

$$p(x)=rac{e^{eta_0+eta_1x}}{1+e^{eta_0+eta_1x}}$$
 $igwedge rac{p(x)}{1-p(x)}=e^{eta_0+eta_1x}$

odds

a little bit of algebra:

$$p(x)=rac{e^{eta_0+eta_1x}}{1+e^{eta_0+eta_1x}} \longrightarrow rac{p(x)}{1-p(x)}=e^{eta_0}$$

 $\log\left(rac{p(x)}{1-p(x)}
ight) = logit(p(x)) = eta_0 + eta_1 x$ log(odds): logit

odds

- the **logit function** (log(odds)) is the **link function** between a linear expression of X and the probabilities of Y
- linear X expression $(\beta_0 + \beta_1 x) \rightarrow \text{logit scale (continuous)}$
- logistic function: converts values on the logit scale back to probabilities

$$\left\{egin{aligned} logit(p(x)) &= eta_0 + eta_1 x \ \sigma(eta_0 + eta_1 x) &= p(x) \end{aligned}
ight.$$
 our objective!

how do we obtain the model coefficients β ?

 similarly to linear regression, we need to define a cost function and then minimise it

observations	predictions	
у	$\hat{y} = \sigma(eta_0 + eta_1 x)$	
		ノ

difference between observed and predicted values

Estimating the coefficients

how do we obtain the model coefficients β ?

 similarly to linear regression, we need to define a cost function and then minimise it

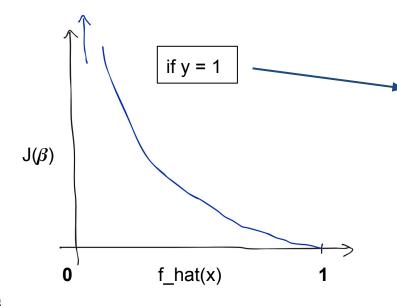

$$J(eta) = \mathsf{Cost}(\hat{y},y) = egin{cases} -log(\hat{y}) & ext{if } y = 1 \ -log(1-\hat{y}) & ext{if } y = 0 \end{cases}$$

$$J(\beta) = \operatorname{Cost}(\hat{y}, y) = -(y \cdot log(\hat{y}) + (1 - y) \cdot log(1 - \hat{y}))$$

Cost function for logistic regression

$$J(eta) = \operatorname{Cost}(\hat{y}, y) = -(y \cdot log(\hat{y}) + (1 - y) \cdot log(1 - \hat{y})$$

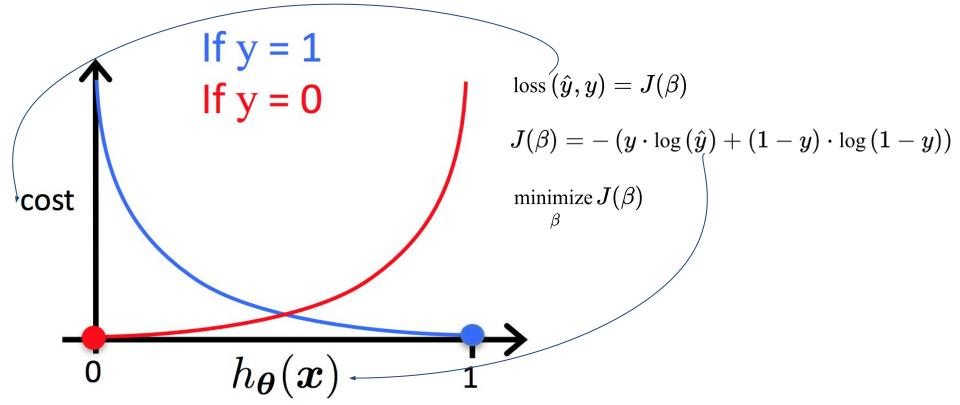

- if y hat = 1, cost = 0
- if y_hat \rightarrow 0 (but y = 1), cost \rightarrow infinity
- the opposite holds if y = 0

ZITEBOARD

Loss function for logistic regression

From: https://datascience.stackexchange.com/questions/40982/logistic-regression-cost-function

Minimising the cost function

- the defined cost function is convex.
- can be minimised by gradient descent
- machine learning perspective: gradient descent is a general algorithm to solve models
- alternatively:
 - maximum likelihood
 - non-linear least squares

Binary classification: measuring performance

- the most common metric to measure the performance of a binary classifier is the **error rate**:

$$\frac{1}{n}\sum_{i=1}^n I(y \neq \hat{y})$$

Confusion matrix

		True observation	
		1	0
Dwadiatian	1	TP	FP
Prediction	0	FN	TN

Not only total error rate!

- **FPR** = FP/(FP+TN)
- **FNR** = FN/(FN+TP)
- TER = (FN+FP)/(FN+FP+TN+TP)

Introducing the dataset

binary phenotypes: **cleft lip** (presence/absence)

Binary classification

		True observation	
		1	0
Due di eti e u	1	TP	FP
Prediction	0	FN	TN

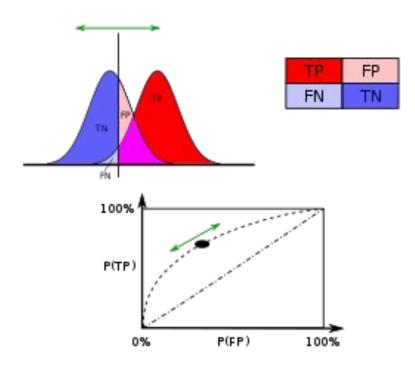

- classify observations in two categories (1/0)
- however, predictions are often probabilities (P(y=1|x))
- different *cut-offs* (e.g. 0.5) will give different results

- Relationship between TPR and FPR
- The diagonal is chance classification (no predictive ability)

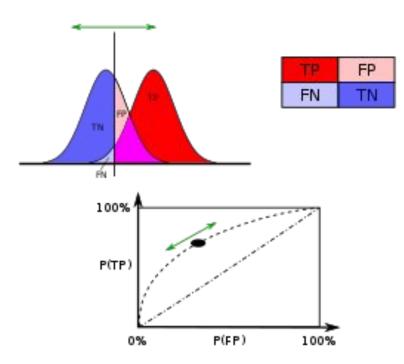

- Relationship between TPR and FPR
- The diagonal is chance classification (no predictive ability)
- Threshold for P(Y=1|x): 0
- No FN, no TN (all positive predictions)
- TPR = TP/TP) = 100%;
- FPR = FP/FP = 100%

		True observation	
		1	0
Due dietie e	1	TP	FP
Prediction	0	0	0

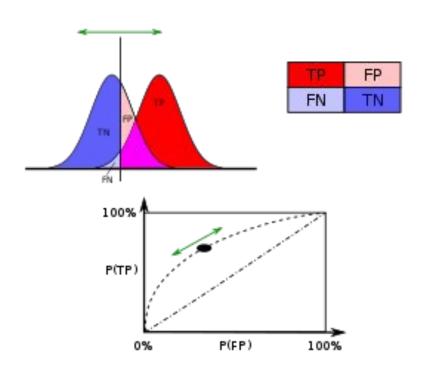

- Relationship between TPR and FPR
- The diagonal is chance classification (no predictive ability)
- Threshold for P(Y=1|x): 1
- No TP, no FP (all negative predictions)
- TPR = 0/FN = 0%;
- FPR = 0/TN = 0%

		True observation	
		1	0
Duo di eti e u	1	0	0
Prediction	0	FN	TN

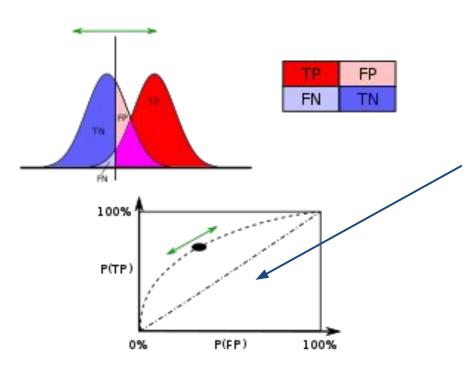

- Relationship between TPR and FPR
- The diagonal is chance classification (no predictive ability)
- The best is towards the left upper corner (TPR → 100%, FPR → 0%)

Area under the curve (AUC)

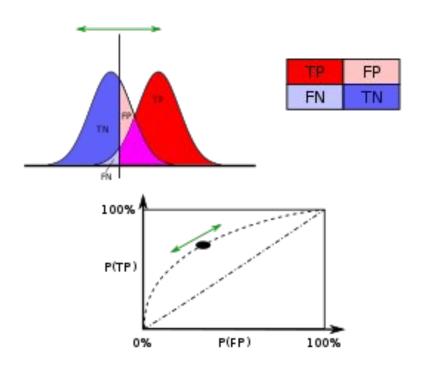

- AUC = 0.5: random guessing
- AUC = 1: perfect classifier
- AUC > 0.8: good classifier

Cut-off thresholds

- Two types of error: FP, FN: sometimes one error may be more critical than the other
- e.g. for a bank may be more important to correctly identify borrowers who will default at the expense of an increase of false positives (and of the total error rate) → lower cut-off for P(y=1|x)
- e.g. in a pandemic, you may want to be sure about detecting carriers, even if this means increasing the FPR
